Specific aims address 1) the effects of the male sex and the female sex hormones, 2) the consequences of alteration in the ratio of nave and progesterin (P)-induced masculinization on CV function in the male offspring, and 3) the differential expression of the two estrogens, 17beta-estradiol (E) and 17-alpha-ethinyl estradiol (EE) in the developing CV system. To date, our research program has revealed that: 1) male sex is the predominant determinant of abnormal fetal cardiac development in a P-treated ovariectomized rat model, 2) altered estrogen exposure during fetal life is responsible for abnormal fetal cardiac development in both male and female offspring, and 3) the major sex-dependent effects of fetal exposure to estrogen occur in the CV system. This proposal addresses the role that estrogen receptor (ER) subtype plays in fetal cardiac development. New research on the human heart will be integrated with our research on the fetal heart. We will use ER gene knockout mice (ER^{-/-} and ER^{+/+}) to determine whether the ER^{-/-} subtype is essential to E-induced feminization of fetal CV function. To determine the effects of ER^{-/-} on fetal cardiac development we will create a mouse model with ER^{-/-} selectively overexpressed in the CV system, using the cre-lox technology. In the second specific aim we will determine the effects of altered ratio of nave to P on male CV development and function. This will be achieved by administering the P analogue, ZK 59794, for 3 days prior to conception. This model will allow us to assess the combined effects of masculinizing (P) and feminizing (E) hormones on male fetal CV development and function. This model will also allow us to examine whether there
