Category:Cumbia music genresCD30 and its ligand, CD30L, play critical roles in both T-cell and B-cell lineages. Two related T-cell surface antigens, designated CD30 and CD30L, are expressed on a small subset of T cells. Both the ligand for CD30 and CD30 itself are transmembrane glycoproteins of the tumor necrosis factor (TNF) receptor family. Tumors in which CD30 is expressed have the potential to undergo spontaneous regression and therapeutic responses to CD30-directed treatments. The goal of this study was to understand the physiologic role of CD30 and CD30L. T-cell receptor (TCR) transgenic mice were used to delineate the expression and function of CD30 and CD30L in lymphocyte subsets. On a cell-intrinsic basis, CD30 was uniquely expressed on all CD8+ T cells that underwent either positive or negative selection, whereas CD30L was uniformly expressed on all CD4+ T cells at all stages of development. Interestingly, CD30/CD30L interactions could act as a TCR costimulatory signal for CD8+ but not CD4+ T cells. CD30 and CD30L also acted on a cell-extrinsic basis to regulate the growth of T cells in a manner independent of TCR signaling. Thus, CD30/CD30L interactions play a critical role in the development, homeostasis, and survival of CD8+ T cells. These data reveal critical biologic functions of CD30/CD30L and emphasize the need to characterize their specific contribution to disease states.Circulating microparticles of endothelial origin in end-stage heart failure. Endothelial activation and subsequent inflammation and remodeling contribute to the development and progression of heart failure. We investigated the number and procoagulant properties of circulating microparticles (MPs) released from endothelial cells in patients with heart failure. Blood samples were obtained from 59 consecutive patients with heart failure and 49 healthy volunteers. Blood samples were analyzed by flow cytometry for cell-derived MPs. The coagulation potential of MPs was investigated by using a Proth 2d92ce491b
