However, this can be a time-consuming effort and may leave the user with poor browsing experience due to network latency. Wireless Area Networks (WAN) 802.11 is an abbreviation for IEEE 802.11a/b/g/n, which stands for "Wireless LAN". IEEE 802.11, which is based on the original IEEE 802 standard, uses the same physical layer as IEEE 802, with the addition of 802.11n, which is a multi-user version. 802.11n was designed for high-speed wireless local area networks in unlicensed frequency bands, and therefore it provides higher throughput than 802.11.802.11 allows users to link devices that are not in physical contact. It does this through a radio link, which is established using a transmitter and receiver.802.11 technology operates in the unlicensed radio spectrum between 2.4 and 5 GHz. Like other IEEE standards, 802.11 technology is a connectionless protocol. Connections are not required or established. Data is exchanged on a best effort basis. 802.11n is backward compatible to 802.11b/g. 802.11n is a faster standard than 802.11b/g and 802.11n with advanced key management. 802.11n allows data to be transferred at a maximum rate of 600 Mbps over either a single-stream or multiple-stream capable radio.The most common applications of 802.11n are: wireless video streaming, file sharing, internet access over mobile devices and embedded networking devices. As of 2012, several mobile phone manufactures have released devices with 802.11n Wi-Fi radios: Android devices such as Samsung Galaxy S3, LG G Pad 8.3, HTC One X and Samsung 2d92ce491b
