In this paper, we introduce an efficient algorithm to find the best matching pattern by using pixels. Our approach implements the following steps: Find the keypoints (e.g. corners, contour or arbitrary points) in the reference image by using SIFT [5, 6], SURF [7] or any other standard technique. Extract local intensity for each detected keypoint by using a gaussian filter (or any other kernel function). Compute the sparse distance matrix from the obtained intensity contour of the reference image (or any other image) by using the following approach: Set the reference and the target image to be the same size. Compute a preliminary alignment using RANSAC [2] Extract the gradient vector field of the image, which implies to compute the object boundary and an approximation of the normal vector. Compute the gradient orientation map where the orientation represents the orientation angle of the gradient vector around each pixel in reference image. From the gradient orientation map we compute a sparse orientation pattern by applying K-means clustering algorithm. Compute the sparse distance matrix from the orientation pattern of reference image. Apply RANSAC to determine the most likely matching pattern in reference image [2, 4, 5]. If two patterns are not aligned, a thresholding algorithm is applied to set them apart. If two patterns are not separated, a method to merge them is applied. Reference image (Figure 1), and the result using this algorithm are shown in Figure 2. Figure 1: Example of a Reference Image (or Pattern) Figure 2: Example of a Matched Image (using the algorithm) Matlab implementation for those who are interested: [Diff, T, Delta] = gradient_match(Ref, Target, K, WindowSize); Thanks for all the algorithm's tips! But it isn't exactly what I am looking for: 1- I'd like a more stable background, without the high contrast in the non-matching areas. 2- Is there a way to avoid the cross-correlation problem? A: Using 2D images as references is not suitable because they are not really suitable for this kind of problem. A very different approach is to use a 3D shape to detect the matching object in the scene. We use the shape parameters to estimate the distance between the query scene and the reference shape,

The proposed algorithm does not rely on any equation for matching but on an entire image, stored in a buffer. In the reference image, a number of different elements are aligned and together form a pattern, described by a set of parameters. The algorithm proceeds by dividing the reference image into an array of blocks, each block is analyzed by a different block pattern. For each block, the following steps are executed: 1) Compute the similarity distance between each element of the reference block and the centers of the candidate blocks. 2) Average the distances for each candidate block. 3) Repeat steps 2 and 3 with a re-initialized buffer array. 4) Is the candidate block most similar to the reference block? 5) If yes, end the processing cycle, otherwise repeat steps 2 to 4 for the next block. File post-processing outputs the most similar block as the match. This is a pretty simple approach, like a single pixel, block by block, sequential comparison in the reference image. There is the possibility that due to the nearest neighbor heuristic, one must consider the potential creation of spurious matches, due to global or local intensity variations. The process is depicted with an example below where the sought pattern is a duck, and the reference image is of a lake. Assume that the candidate block is "a drownd fowl" and that the reference block "Water birds" The block centers are the following: Reference block: Center coordinates $x, y = [0.615322 \ 0.010432]$; Block pattern: Block matches $[0.1 \ -0.5 \ -0.1 \ 0.1 \ -0.1 \ 0.1 \ -0.1]$; Block centers are $[0.5 \ 0.1 \ -0.5 \ 0.1 \ 0.1]$; The following represents the distance of each element of the reference block (white) to the candidate blocks centers (black): Assume that the block centers are in the following point: $X = 0.038 \ Y = -0.008$ As can be seen in the figure the distances are lower, therefore block "a drownd fowl" is the most similar. Defining the pattern centers is as straightforward as having the cluster where the block to find lies. This makes it possible to implement a much simpler core compared with the classical Nearest Neighbor approach. 09e8f5149f

***** In this code there is implemented the algorithm described in T. K. Lachkar (2002). Real-time pattern matching and detection using a dynamic finite image database. IEEE Trans. PAMI, 24 (8): 739-47. ***** In the first step the input image is firstly scaled down to 80x80 pixels. Then an auxiliary image is generated by assuming that the input image is tilted of an angle of 10 deg. The image is flipped in respect to the orientation of the input image. Finally the auxiliary image is rectified in respect to the input image. Sample Input image: Input image to be matched with a target template that has the same size: The Matlab function % C. K. We present a new approach, based on multiscale image registration, in order to overcome those problems.

What's New In?

1. Load the reference image, its rotation angle and the number of grid elements along the vertical and horizontal directions. 2. Compute the slope (gradient) along the vertical or horizontal direction of the reference image. 3. Find the global maximum of the matching score by making the search along the direction with the maximum gradient. 4. Cross-correlate the reference and input images. Use the maximum correlation score to build the matching score. 5. Construct the matrix whose elements are the matching scores of all grid elements. You are facing the below problem while you are trying to implement this algorithm. I read your code and I need to help you to resolve this error. You can contact to me on WhatsApp at 9499665512 with your phone no. Below is the image attached: Please let me know if anyone can help me to resolve this error. A: You can use the following set of functions to perform the pattern matching which was shown in the image. I think the problem is with the rotation angle which you have mentioned. Please apply the rotation angle before performing the pattern matching. Get the index of the maximum element in each row and column. '>> iImgRef = imread(fullfile(imdir,'RefImg.tif')); '>> angle = 0; for i=1:size(iImgRef,1) for j=1:size(iImgRef,2) imRotate(iImgRef,angle,j,i); max = max(max(iImgRef(:,j,1)),max(iImgRef(:,j,2))); maxInd = max+1; end end Now, use the indices to find the maximum element of each row and column of the input image % indx = (maxInd-1)*size(iImgRef,1)+iImgRef(:,j,1); % indx = (maxInd-1)*size(iImgRef,1)+iImgRef(:,j,2); And, finally, do the pattern matching % imRotate(inputImg,angle,1,1) % imRotate(inputImg,angle,2
