Tunable transition state selection in intermolecular cycloaddition of azomethine ylides to benzofuran and biphenyl: the crystal structure of the vinylidene intermediate. The mechanism of the intramolecular cycloaddition reaction of diphenyl or benzofuran azomethine ylides with acetylenes has been studied using density functional theory (DFT). The calculated activation energy, enthalpy, and Gibbs free energy of the reaction indicate that the initial step of the reaction is the stepwise S(N)2 displacement of the ylide by the acetylene. The subsequent step in the reaction is the nucleophilic addition to the alkyne intermediate to form an [nucleophilic intermediate, electrophilic intermediate] complex. The alternative steps would be the elimination of the acetylene or the ylide from the complex. The following factors have been found to affect the overall reaction rate: (a) diphenyl and benzofuran azomethine ylides are more reactive than pyrrolidinomethyl az
