Professional image editors tend to use the Batch Optimizer so that one file can be processed with the settings for a number of other files of the same type. The Batch Optimizer dialog box enables you to create a script or a macro that can be applied to many files in one click. You can open the dialog box from Image • Scripts • Optimize Batch. The following sections offer an overview of the various tools and techniques you can use in Photoshop. For more details on the specifics of Photoshop tools and techniques, refer to the Photoshop manual. Understanding Photoshop tools and commands Understanding the tools in Photoshop is one of the most important skills to have. Not only is a tool like the Eraser or the Adjustment Brush an integral part of most graphics-producing Photoshop actions, but many tools are used in some of the more advanced manipulations. Using a specific tool in the right way, and understanding what each tool does, enables you to create truly beautiful images. Erasing and Redrawing tools Using the Eraser and the Redrawing tools, you can remove or redraw pixels in a bitmap image. The Eraser tool allows you to erase areas of pixels, while the Redrawing tool creates new pixels to replace areas of pixels you've deleted with the Eraser tool. Although the Redrawing tool is far more useful than the Eraser tool, most professionals use the Eraser tool because it erases pixels, while the Redrawing tool requires the image to be saved, which makes it more difficult to use. Using the Redrawing tool is easy. Just press Shift+E on the keyboard to display the Eraser tool on the Toolbox palette and then drag across an area of an image that you want to erase. To create a new pixel, drag over a point on the image that you want a new pixel to replace. As long as your new pixel is to the right of the old pixel, the old pixel will be erased and replaced with the new pixel, and the result will appear as a blank area. If you select a large area in your image with the Eraser tool, the result is a bitmap or raster image that contains the area of pixels you selected. If you want to remove a large area of the original pixels and replace them with new pixels, you need to save the image so that you can create a new image. To save an image, either use the Save As command

1. Field of the Invention The present invention relates to a liquid crystal display device, and more particularly, to a liquid crystal display device in which a condensing plate is provided on the back side of a light guide plate of a light guide type and a light is condensed by the condensing plate to achieve condensing and uniforming effects and the thickness and width of the device are reduced. 2. Discussion of the Related Art A liquid crystal display device is widely used as a display device of a computer, a television, and a portable information device. In recent years, a liquid crystal display device is proposed which is applied to a portable information device and is provided with a light guide plate in order to prevent decrease in the visibility due to the reflection and high contrast. The liquid crystal display device is provided with a light guide plate which is disposed on the upper surface thereof and guides a light incident from the back surface of the light guide plate. In this liquid crystal display device, the light incident from the back surface of the light guide plate is transmitted to the front surface thereof, passes through a liquid crystal layer formed on the front surface thereof, and then emitted toward the front surface of the light guide plate. In this way, a back light type liquid crystal display device which achieves visibility by the transmitted light is proposed. However, in the above liquid crystal display device, the light incident from the back surface of the light guide plate is transmitted to the front surface of the light guide plate through a large area. For this reason, the light intensity distribution on the front surface of the light guide plate becomes uneven. Accordingly, it is difficult to achieve uniform luminance of a liquid crystal display panel. A liquid crystal display device is proposed which is provided with a light guide plate having a plurality of slits and a sheet for condensing the light propagated through the light guide plate from the back surface thereof (refer to JP-A No. 05-121624). This liquid crystal display device has a merit that the size and thickness of the liquid crystal display device can be decreased, because the light guide plate is formed by a film. However, light is not condensed in the portions where no slit is formed on the back surface of the light guide plate in the liquid crystal display device described in JP-A No. 05-121624. Accordingly, the light intensity distribution on the front surface of the light guide plate becomes uneven. Therefore, it is difficult to achieve uniform luminance of a liquid crystal display panel.

1. Field of the Invention The present invention relates to an optical control element, for example, an optical control element used as an optical element such as an electro-optic crystal, an optical switch, an optical modulator, a light deflector, a light modulator, an optical shutter, and a polarizer, or an optical filter used in, for example, a luminance-control device of a liquid crystal display (LCD), a video camera, a digital camera, a television receiver, or a projector. 2. Description of the Related Art An optical control element, for example, a liquid crystal electro-optic element, is widely used as a display device for displaying images and the like. Among such liquid crystal electro-optic elements, for example, an optical control element which uses a ferroelectric liquid crystal (FLC) as the liquid crystal has recently been actively studied and developed. This optical control element uses the liquid crystal phase change accompanied by the application of an electric field. For example, if an electric field is applied to a liquid crystal layer sandwiched between electrodes, the liquid crystal molecules are tilted and twisted. A display based on a twisted light is thereby realized. The liquid crystal molecules are tilted in the direction of the electric field, for example, if the amplitude of an applied voltage is large; however, if the applied voltage is small, the liquid crystal molecules are tilted in a direction parallel to the electrode. If the tilted direction of the liquid crystal molecules is fixed, the incident light undergoes optical modulation, whereby a white display or a black display is displayed. The liquid crystal molecules can be rotated in the plane of a substrate. For example, if the helical axis directions of liquid crystal molecules are rotated by 90° in the horizontal direction by making use of the helical axis structure of the liquid crystal molecules, the reflected light is thereby twisted by 90° in the same plane. Then, the incident light undergoes optical modulation. In this manner, an optical control element having an excellent viewing angle property can be realized. In order to drive such a liquid crystal electro-optic element, the following methods have been commonly used: a simple matrix method and an active matrix method using thin film transistors (TFTs). In the active matrix method, for example, in an active matrix drive liquid crystal electro-optic element, a TFT as a switching element for selecting the pixel is disposed in each pixel. In the active matrix drive liquid
